

AKA-CLAUDE-TOOLS · QUICKSTART · JUNE 2026 · V0.2.0

Set it up safely.

A hardened Claude Code in **four steps** — without becoming a terminal expert. Spin up a working copy of your setup, or harden the one you already use.

4 steps

2 install paths

side-by-side or in-place

reversible

github.com/alsoknownassecurity/aka-claude-tools

BEFORE YOU START

Two ways in. Same destination.

PATH A • RECOMMENDED

Hand it to your AI

Paste the repo link into Claude Code — it clones the kit, reads the guide, and does the setup. No commands you type, no manual clone.

PATH B

Run the installer

Prefer the terminal? Clone it yourself, then one script walks you through profile, alias, and additions.

Both end the same way: a **hardened profile with its own launcher** — in a fresh folder to try it, or your real config to harden in place.

1 Get the kit.

Recommended: don't clone anything yourself — give Claude Code the repo link (Step 2, Path A) and it fetches the kit for you.

```
# or, for the terminal route (Path B), clone it yourself:  
git clone git@github.com:alsoknownassecurity/aka-claude-tools  
./install.sh --version    # confirm you've got v0.2.0
```

MIT, open-source. Nothing runs on download — read the code first if you like; it's all there.

2 Hand it to your AI.

In Claude Code, say:

"Set up aka-claude-tools from github.com/alsoknownassecurity/aka-claude-tools — read its agent-install.md and set up a new hardened profile for me."

It clones the repo, reads the guide, checks what you already have, migrates anything custom, and runs the installer for you. You stay in the chat — **no commands to type, no manual clone.**

2 Or run the installer.

```
./install.sh          # interactive setup  
./install.sh --defaults # the recommended six
```

It asks where to put the profile (default `~/.claude-aka`), what to name the launcher (default `aka`), and which additions to switch on.

STEP 3 OF 4 · LAUNCH IT

3 A separate, hardened agent.

```
aka # launches the isolated, locked-down profile
```

The installer adds one launcher — `aka`. Run it and you're in a Claude Code with its **own settings, hooks, and history** — your normal `claude` left as-is. (Or skip the alias and harden `~/.claude` directly.)

4 Test that it actually fires.

- ✓ Ask it to read `~/.ssh/id_rsa` — it should **refuse**.
- ✓ Check the status bar — context and rate-limit gauges should show.
- ✓ Try `curl ... | bash` — the guard should **block** it.

Verify the control, not the setting. A guardrail you haven't watched fire is a guardrail you're only assuming works.

LOW COMMITMENT, BY DESIGN

Change your mind anytime.

- Turn any addition **on or off** — they're independent; re-run anytime to adjust.
- Tried it in a fresh profile? **Delete it** — your real setup never changed. Installed in place? **Re-run and deselect.**
- Run several side by side — **aka** secured, **work**, **play** — **each its own launcher & toolkit.**

Low stakes by design: try it isolated, or harden your real config and back out clean.

THAT'S IT

A safer agent, in minutes.

Four steps, fully reversible — try it in a fresh profile or harden the setup you already use. The deep dive on each piece lives in the companion "[What's inside](#)" deck.

✓ **Get it** → **install** (AI or terminal) → **launch** → **verify**.
